OUTLINE

Daily concentrations of Alternaria spores in Emilia-Romagna

Introduction of synthetic indicators (from daily airborne concentrations to annual values)

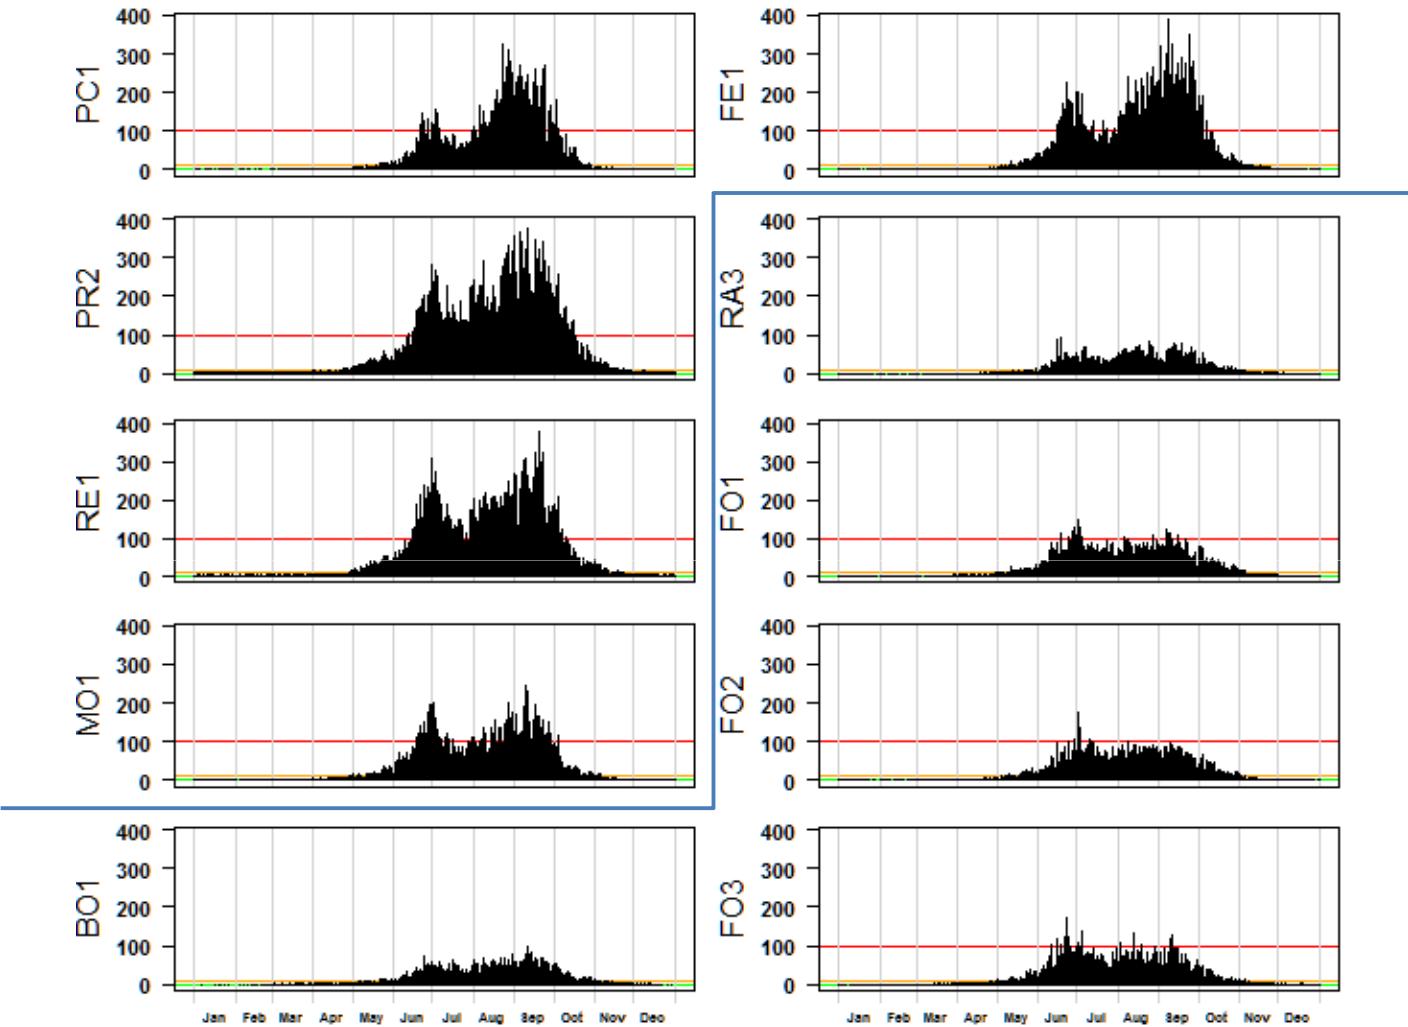

Characterization of Alternaria spore production period (geographical analysis)

Temporal trends of Alternaria indicators (statistical analysis)

Aerobiological network in Emilia-Romagna

Concluding remarks

Analysis of Alternaria spores distribution in 10 monitoring stations

Alternaria spores are present during a large portion of the year in Emilia-Romagna (4,5 months, from end-May to mid-October)

Very significant spatial auto-correlation for pollen production indicators; significant also for some phenological indicators

The length of Alternaria season shows a significant increase during recent years (approximately 1 d/year) mainly due to a significant delay in the ending date, but also to a starting date significant advance

Amount of Alternaria spores is slightly decreasing on average, but trends are significant only locally
